

Thousands of people in the UK are out of work due to long COVID

Tuesday 23 May 2023, by [ALWAN Nisreen](#), [AYOUBKHANI Daniel](#) (Date first published: 22 May 2023).

Studies from multiple countries have found that long COVID is linked to an increased likelihood of not working. Here's what's happened in the UK.

Almost [2 million people](#) in the UK are estimated to be living with long COVID – after-effects of COVID that can persist for months or even years after the initial infection.

Common symptoms include fatigue, breathlessness, muscle and joint pain, cognitive impairment and sleep disruption. People with long COVID also have a [higher risk](#) of developing serious heart and lung problems, stroke and blood clots compared to those who have not previously been diagnosed with COVID.

Studies from multiple countries have found that long COVID is linked to an increased likelihood of not working. For example, [US research](#) found long COVID was associated with 23% higher odds of being unemployed and 16% lower odds of working full-time (25% for those with cognitive symptoms).

We analysed data from the [Office for National Statistics](#) (ONS) to assess the situation in the UK, and similarly found long COVID to be strongly associated with being out of work.

Economic inactivity and long-term absence

Our analysis, published by the ONS, considers data collected [from 206,000 respondents](#) to the coronavirus infection survey. This survey was conducted by the ONS and included questions on long COVID from February 2021 until March 2023, comprising a large, randomly selected sample of UK households.

We aimed to explore the relationship between long COVID and being out of employment while not looking for work (economic inactivity), or long-term absence while in employment.

Importantly, the coronavirus infection survey data provided access to monthly measurements taken from the same people. This allowed us to evaluate labour market status both before and after COVID infection, rather than making comparisons between different people at one point in time.

The people in our sample were working-age adults, excluding anyone in full-time education. For those reporting long COVID seven to 12 months after an initial COVID infection, the odds of being out of employment and not looking for work (excluding due to retirement) were roughly 40% higher compared with the period before having COVID.

This relationship was strongest for people aged 50 to 64, where higher odds of inactivity compared with pre-infection peaked at a 71% increase among those reporting long COVID seven to nine months post-infection.

We also saw that among people in employment, those reporting long COVID four to seven months after first having COVID were over 40% more likely to be absent from work for at least four weeks compared with pre-infection.

However, this increased likelihood didn't persist for people still reporting long COVID beyond seven months after an infection. This may reflect people returning to work (with or without persistent symptoms) upon completing the 28-week [statutory sick pay](#) period.

It might also suggest participants with the most severe illness had already left employment by seven months after an infection, and therefore were no longer in our sample.

Putting these findings into context

Economic inactivity rates in the UK have risen during the pandemic. Half a million more working-age adults were out of employment primarily due to ill health [in mid-2022 compared with 2019](#).

Based on [prevalence estimates of long COVID](#), considered with the calculations we set out above and excluding retirement, we estimate the number of working-age, non-students in the UK who were inactive because of long COVID symptoms was 27,000 in July 2022.

This represents [0.5% of total economic inactivity](#) in the working-age population of non-students during the same period.

It's worth noting that our analysis probably doesn't reflect the full range of employment-related consequences of long COVID. For example, we were unable to assess the effect on working hours due to lack of data.

But research by the [Institute for Fiscal Studies](#) suggested that long COVID may have resulted in the loss of 4.4 million working hours per week in the UK.

Another analysis incorporating data from the [understanding society study](#) estimated that cumulatively, 80,000 people in the UK had [left employment](#) due to long COVID by March 2022.

It's also possible that the working capacity of family members of people with long COVID is affected. For example, they might need to reduce their working hours to provide care and support for loved ones, but there's limited research on this at present.

What could help?

Long COVID symptoms are often [fluctuating or episodic](#), making it tricky to recognise recovery, which can be confused with remission (disappearance of symptoms for a length of time). This is

likely to make return to a fixed pattern of work difficult, particularly in the absence of job flexibility.

It's important to consider the potential widening of health, social and economic inequalities in society because of this, as often the higher paid jobs are more flexible in terms of hours and location of work.

In a [recent survey](#) of more than 3,000 people with long COVID, two-thirds of those who chose to take part reported having experienced unfair treatment at work. Almost one-quarter of respondents said their employer had questioned whether they have long COVID or the effect of their symptoms.

The [all-party parliamentary group](#) for coronavirus in the UK has recommended that the UK government should recognise long COVID as an occupational disease for all key workers. They have also urged the UK government to produce guidelines for employers in both private and public sectors to help employees manage the effects of long COVID.

For the sake of public health and productivity, supporting people with long COVID and other episodic chronic illnesses to navigate job arrangements should be a priority for governments, employers and wider society. Negative attitudes towards long COVID at work can reinforce the [high levels of stigma](#) we know people with the condition experience.

Prof Nisreen Alwan is a Professor of Public Health at the University of Southampton and an Honorary Consultant in Public Health at University Hospital Southampton NHS Foundation Trust. She does research around how to prevent disease and optimise the wellbeing of young families leading to better long-term health and focusing on narrowing health inequalities. Prof Alwan has contributed to the public health response to the pandemic, particularly focusing on the recognition and the quantification of morbidity from COVID19, having initiated the call to Count 'Long COVID'. She was awarded an MBE for services to Medicine and Public Health during the COVID19 pandemic in the Queen's New Year Honours 2021. She was also named amongst other inspiring and influential women from around the world in the BBC 100 Women 2020 list. She is now doing research on Long Covid particularly focusing on inequalities in prevention, recognition and care.

Principal Statistician at the Office for National Statistics, the UK's largest independent producer of official statistics and its recognised national statistical institute, and PhD student at the University of Leicester's Real World Evidence Unit.
